

Dense Deposit Disease

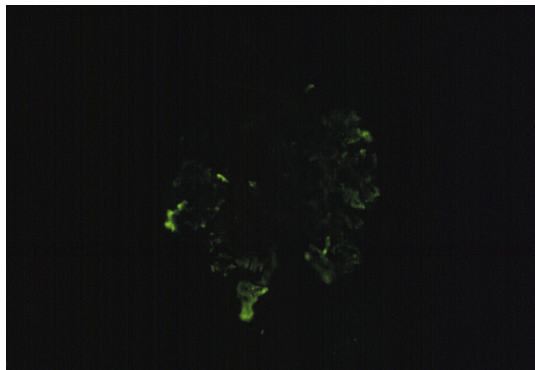

Agnes Fogo, MD

The AJKD Atlas of Renal Pathology presents a compilation of figures on a specific pathologic entity. You may download the figures to create your own personal, non-commercial library of images or to create slides for teaching purposes.

Fig 1. Dense deposit disease is also called membranoproliferative glomerulonephritis type 2 based on the similar light microscopic findings in the two conditions. Mesangial proliferation, double contours of the glomerular basement membrane, and mesangial interposition are evident in this figure. No obvious deposits, which typically appear pink on this PAS-methenamine silver stain, are visualized. The refractile, ribbon-like appearance of the basement membrane is a clue to the correct diagnosis of dense deposit disease, which is confirmed by immunofluorescence and electron microscopy (Jones' silver stain; original magnification, $\times 400$).

Fig 2. Dense deposit disease stains strongly for complement in an irregular, segmental capillary wall distribution, with occasional mesangial staining. Immunoglobulin staining is typically absent, indicating there are no true immune complex-type (ie, antibody-antigen) deposits (immunofluorescence with anti-C3; original magnification, $\times 200$).

Fig 3. Dense deposit disease also may show large, globular mesangial staining for C3, in addition to the capillary wall staining (immunofluorescence with anti-C3; original magnification, $\times 400$).
