

Cytomegalovirus Infection

Agnes Fogo, MD

The AJKD Atlas of Renal Pathology presents a compilation of figures on a specific pathologic entity. You may download the figures to create your own personal, non-commercial library of images or to create slides for teaching purposes.

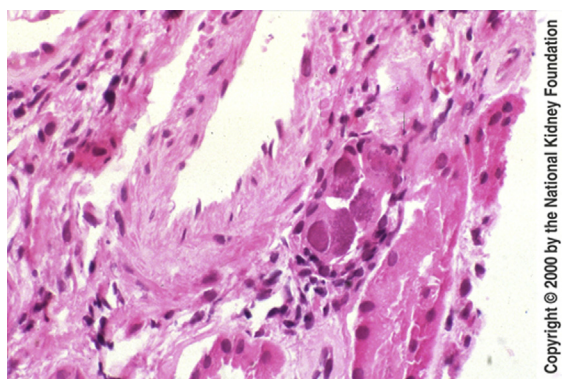

Fig 1. Cytomegalovirus infection is diagnosed by the appearance of large cells with basophilic enlarged nuclei with inclusions. There is frequent tubular injury and degeneration. Cytomegalovirus infection most commonly affects tubular epithelial cells and occurs most commonly in the transplant. (Hematoxylin and eosin, original magnification $\times 100$).

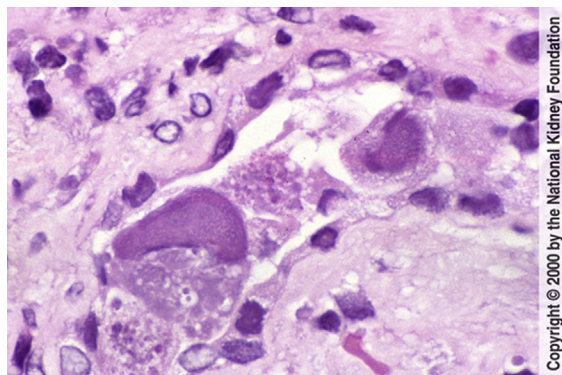

Fig 2. The marked enlargement of the tubular epithelial cells with markedly enlarged nuclei and degeneration is evident in this case of cytomegalovirus infection in the transplant. (Hematoxylin and eosin, original magnification $\times 1,000$).

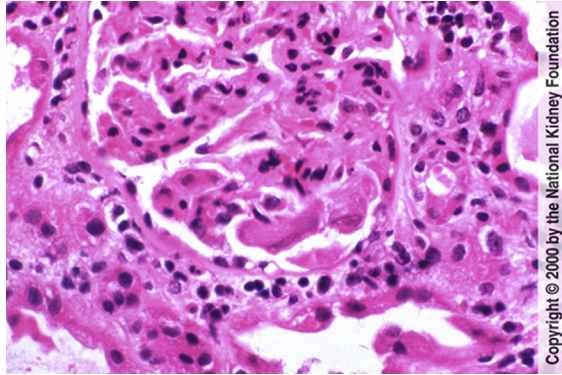

Fig 3. Cytomegalovirus infection may also rarely involve the glomerulus, as in this transplant patient where there is marked enlargement of visceral epithelial cells with enlarged nuclei and owl's eye type nuclear inclusions (left). (Hematoxylin and eosin, original magnification $\times 400$).

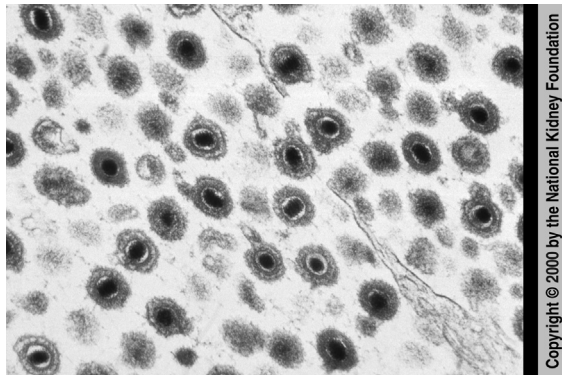

Fig 4. Cytomegalovirus can also be seen by electron microscopy. The virus has a typical bull's eye appearance when present in the cytoplasm, where it has picked up an extra layer of the nuclear membrane. (Transmission electron microscopy, original magnification $\times 200,000$).
